# Victorian Rock Lobster Fishery Stock Assessment: 2012/13 Fishing Season 

March 2014

Adrian Linnane, Richard McGarvey, John Feenstra and Dave Reilly

# Victorian Rock Lobster Fishery Report: 2012/13 Season. 

## Summary

- In 2012/13, the total allowable commercial catch (TACC) was fully taken in both zones. The logbook estimated catches for the Western and Eastern Zone rock lobster fisheries were 258 t of the 260 t TACC and 48 t of the 51 t TACC respectively for the 2012/13 fishing year, which is considered to be fully caught.
- Nominal catch per unit effort (CPUE) has increased in both zones over the last three to four seasons. In 2012/13, the Western Zone CPUE was $0.53 \mathrm{~kg} /$ pot-lift, reflecting a $43 \%$ increase from the historical low in $2009 / 10$ of $0.37 \mathrm{~kg} / \mathrm{pot}$-lift. In the Eastern Zone, the 2012/13 CPUE was $0.51 \mathrm{~kg} /$ pot-lift, an increase of $38 \%$ from $0.37 \mathrm{~kg} / \mathrm{pot}$-lift in 2008/09..
- Current increases in CPUE reflect the above average model estimated recruitment to 60 mm carapace length (CL) in 2007/08 and 2008/09. These increases are confirmed by results from fixed-site surveys in both zones that highlight increases in pre-recruit indices from 2007/08 to 2010/11.
- While commercial CPUEs are currently increasing in the Western Zone, it is important to note that recruitment to 60 mm CL was considerably below average in 2009/10. The time period from recruitment to legal size is approximately four years, suggesting that fishery recruitment in 2013/14 may be reduced. The pre-recruit index from fixed-site surveys has also decreased in this zone over the last two seasons.
- Western Zone egg production in 2012/13 was $74 \%$ of the egg production in the reference year 2001/02 (above the $35 \%$ limit). Available biomass was $75 \%$ of the available biomass at 2001/02 (below the 159\% target).
- A 230 t Western Zone TACC is required for the 2014/15 quota year to maintain biomass rebuilding on the target trajectory to 2020/21 based on a $50 \%$ probability forward projection.
- Eastern Zone egg production in 2012/13 was $152 \%$ of the egg production in the reference year 2001/02 (above the limit of 104\%). Available biomass in 2012/13 was $136 \%$ of available biomass in 2001/02 (below the 184\% target).
- The model $50 \%$ probability forward projection indicates that for a fully taken Eastern Zone TACC of 59 t , the available biomass would rebuild to the target by 2020/21.
- In the Western Zone the model biomass trajectory is consistent with the upward trend observed in nominal CPUE from 2010/11 to 2012/13. In the Eastern Zone, the model biomass trajectory has also continued to increase despite a marginal decrease in nominal CPUE from 2011/12 to 2012/13.
- The observed trends are consistent with previous advice in relation to the resource. The fishery has experienced an increase in CPUE resulting from above average recruitment to 60 mm CL in 2007/08 and 2008/09. In the Western Zone, recruitment declined to below average levels in 2009/10 indicating that the available biomass will not maintain its rebuild to the 2020/21 target at the current TACC of 260 tonnes. In the Eastern Zone, recruitment is consistent with the long-term average indicating that a TACC increase to 59 tonnes may be considered for $2014 / 15$ whilst maintaining the biomass trajectory to the target.

# Key Fishery Statistics 

## 1) Catch, Effort and CPUE

## Western Zone

The logbook estimated catch for the 2012/13 fishing year (Nov-Sept) was 258 t (Table 1). Effort in 2012/13 was 483,000 potlifts, reflecting a $26 \%$ decrease since 2009/10 (650,000 potlifts). As a result of decreasing effort, catch rate has increased (Figure 1). In 2012/13, nominal CPUE was $0.53 \mathrm{~kg} /$ potlift reflecting a $43 \%$ increase since 2009/10 ( $0.37 \mathrm{~kg} /$ potlift) and the highest estimate since 2004/05 ( $0.61 \mathrm{~kg} /$ potlift). The 2012/13 season represents the fourth consecutive year that the TACC was fully taken (Table 2).

## Eastern Zone

The logbook estimated catch for the 2012/13 fishing year (Nov-Sept) was 48 t (Table 3). Effort was 94,000 potlifts, reflecting a $37 \%$ decrease from 2010/11 (150,000 potlifts). Nominal CPUE has increased by $38 \%$ from $0.37 \mathrm{~kg} /$ potlift in $2008 / 09$ to $0.51 \mathrm{~kg} /$ potlift in 2012/13 (Figure 2). The 2012/13 season also represents the third consecutive year that the TACC was fully taken (Table 4).

## 2) Pre-recruit indices and recruitment

Current CPUE trends reflect recent increases in both model estimated recruitment and prerecruit indices. Model estimated recruitment to 60 mm CL was above average in both zones in 2007/08 and 2008/09 (Figure 3). Pre-recruit indices from fixed-site surveys increased from 2007/08 to 2010/11 (Figure 4). Recruitment to 60 mm CL subsequently entered the fishery three to four years later and reflects the current legal size CPUE increases observed in both zones over the last three to four seasons.

While CPUEs are currently increasing in the Western Zone, it is important to note that recruitment to 60 mm CL was considerably below average in 2009/10 (Figure 3). The time period from recruitment to legal size is approximately four years, suggesting that fishery recruitment in 2013/14 may be reduced. The pre-recruit index from fixed-site surveys has also decreased in this zone over the last two seasons (Figure 4).

## 3) Puerulus Settlement

Trends in puerulus settlement support current recruitment estimates (Figure 5). Increases to recruitment (at $60 \mathrm{~mm} C L$ ) in 2007/08 and 2008/09 correlate with high levels of puerulus settlement observed across south-eastern Australia in 2005/06 and 2006/07 (two year lag). Further correlations suggest that the period from 60 mm CL to the minimum legal size is a further three to four years (Figure 6). In total, this indicates a period of five to six years from settlement to legal size within Victoria.

## 4) Model outputs

## Western Zone

The latest stock assessment model outputs estimate Western Zone egg production in 2012/13 to be at $74 \%$ of the egg production in the reference year 2001/02, and is therefore above the $35 \%$ limit (Figure 7). Available biomass in 2012/13 was $75 \%$ of the available biomass at 2001/02 and is below the 159\% target (Figure 8). A 230 t TACC is required for the 2014/15 quota year to maintain biomass rebuilding on the target trajectory based on a $50 \%$ probability forward projection (Figure 9).

## Eastern Zone

Eastern Zone egg production in 2012/13 was 152\% of the egg production in the reference year 2001/02, which is above the limit of 104\%) (Figure 10). Available biomass in 2012/13 was 136\% of available biomass in 2001/02 and is below the 184\% target (Figure 11). The model $50 \%$ probability forward projection indicates that for a fully taken TACC of 59 t , the available biomass would rebuild to the target by 2020/21 (Figure 12).

Table 4. Eastern Zone history of TACCs for each quota period from 2002-03 to 2012-13 (TACC: Total Allowable Commercial Catch).

Figure 2. Eastern Zone CPUE from 1978-79 to 2012-13.

Relative abundance

Relative abundance

Figure 4. Western (top) and Eastern (bottom) Zone fixed-site monitoring CPUE trends.

Figure 5. Model estimated recruitment to 60 mm CL in the Western Zone fishery (red line) with puerulus settlement from Port Campbell (blue line) and Apollo Bay (pink line), lagged by two years. Note: Absence of puerulus data at Apollo Bay (2007-2008) due to harbour development.

Figure 6. Comparison of model estimated recruitment to 60 mm CL in the Western Zone fishery (red line) with legal sized (black line) lagged by four years.

Figure 7. Model estimated level of egg production through time in the Western Zone (with $75 \%$ probability; blue line). Limit reference point ( $35 \%$ of egg production in 2001/02; dashed red line).

Figure 8. Model estimated levels of available biomass in the Western Zone (with 50\% probability; red line). Target reference point ( $159 \%$ of available biomass in 2001/02; dashed green line). Projected available biomass (dashed red line) given a TACC of $230 \mathrm{t} / \mathrm{yr}$ to rebuild available biomass to the biological reference point target by 2020/21.

Figure 9. Western Zone projected available biomass at a TACC of 230 t (blue line) versus projection at 260 t (red line).

Figure 10. Model estimated level of egg production through time in the Eastern Zone (with 75\% probability; blue line). Limit reference point (104\% of egg production in 2001/02; dashed red line).

Figure 11. Model estimated levels of available biomass in the Eastern Zone (with 50\% probability; red line). Target reference point (184\% of available biomass in 2001/02; dashed green line). Projected available biomass (dashed red line) given a TACC of $59 \mathrm{t} / \mathrm{yr}$ to rebuild available biomass to the biological reference point target by 2020/21.

Figure 12. Eastern Zone projected available biomass at a TACC of 59 t (blue line) versus projection at 51 t (red line).

## Definitions

$\left.\begin{array}{ll}\text { Available biomass } & \begin{array}{l}\text { An estimate of the size (weight) of rock lobsters that are above } \\ \text { legal minimum length and can be harvested. }\end{array} \\ \text { Catch per unit effort - } \\ \text { A measure of the density or population size of rock lobsters in the } \\ \text { A fishery. It is expressed as the effort required to harvest a defined } \\ \text { amount of catch. The data has not been altered to remove } \\ \text { irregularities in the catch records. }\end{array}\right\}$
