# Victorian Rock Lobster Fishery Stock Assessment 2013 

February 2013

Adrian Linnane, Rowan Chick, Terence Walker, Fabian Trinnie and Dave Reilly

# Victorian Rock Lobster Fishery Report 2013 

Adrian Linnane, Rowan Chick, Terence Walker, Fabian Trinnie and Dave Reilly

## Summary

- The logbook estimated 2011/12 Fishing Year (Nov-Sept) catch for the Victorian Western and Eastern zone rock lobster fisheries were 233 and 62 t respectively. In 2011/12, the Total Allowable Commercial Catch (TACC) was fully taken in both zones for the second consecutive season.
- Nominal catch per unit effort (CPUE) has increased in both zones over the last 2-3 seasons. In 2011/12, the Western Zone CPUE was $0.49 \mathrm{~kg} /$ potlift, reflecting a $32 \%$ increase from 2009/10 ( $0.37 \mathrm{~kg} /$ potlift). In the Eastern Zone, the 2011/12 CPUE was $0.54 \mathrm{~kg} /$ potlift, an increase of $46 \%$ from 2008/09 ( $0.37 \mathrm{~kg} /$ potlift).
- Current increases in CPUE reflect the high model estimated recruitment to 60 mm carapace length (CL) in 2007 and 2008 now entering the fishery. These increases are confirmed by results from fixed site surveys in both zones which highlight high pre-recruit indices from 2008-2010. However, while commercial CPUEs are currently increasing, it is important to note that recruitment to 60 mm CL decreased from 20092011 suggesting that fishery recruitment after 2013 may be reduced.
- Western Zone egg production in $2011 / 12$ was $74 \%$ of the egg production in the reference year 2001/02 (well above the $35 \%$ limit). Available biomass was $75 \%$ of the available biomass at 2001/02 (well below the 173\% target). To rebuild to the 2020/21 target, the model estimates that a TACC of 259 t is required, based on a $50 \%$ probability.
- Eastern zone egg production in 2011/12 was $148 \%$ of the egg production in the reference year 2001/02 (above the limit of 104\%). Available biomass in 2011/12 was $126 \%$ of available biomass in 2001/02 (well below the 219\% target). To rebuild to the 2020/21 target, the model estimates that a TACC of 51 t is required, based on a $50 \%$ probability.
- In both the Western and Eastern Zones, the model biomass trajectory is consistent with the upward trend observed in nominal CPUE from 2009/10 to 2011/12.
- The observed trends are consistent with previous advice in relation to the resource. The fishery is currently experiencing an increase in CPUE resulting from above average recruitment to 60 mm CL in 2007 and 2008. This recruitment is expected to continue into 2012/13 before weakening as evidenced by reduced recruitment estimates post 2008. As a result, existing TACCs should protect current recruitment to ensure that biomass rebuilding continues to occur.

## Key Fishery Statistics

## 1) Catch, Effort and CPUE

## Western Zone

The logbook estimated Fishing Year (Nov-Sept) catch for 2011/12 was 233 t (Table 1). Effort in 2011/12 was 475,000 potlifts, reflecting a $27 \%$ decrease since 2009/10 (650,000 potlifts). As a result of decreasing effort, catch rate has increased (Figure 1). In 2011/12, nominal CPUE was $0.49 \mathrm{~kg} /$ potlift reflecting a $32 \%$ increase since 2009/10 ( $0.37 \mathrm{~kg} / \mathrm{potlift}$ ) and the highest estimate since 2005/06 ( $0.51 \mathrm{~kg} /$ potlift). The 2011/12 season represents the second consecutive year that the TACC ( 240 t ) was fully taken (Table 2).

## Eastern Zone

The logbook estimated Fishing Year (Nov-Sept) catch for 2011/12 was 62 t (Table 3). Effort in 2011/12 was 114,000 potlifts, reflecting a $24 \%$ decrease since 2010/11 ( 150,000 potlifts). Over the last three seasons, catch rate has increased by $46 \%$ from $0.37 \mathrm{~kg} /$ potlift in 2008/09 to $0.54 \mathrm{~kg} /$ potlift in 2011/12 (Figure 2). The 2011/12 season also represents the second consecutive year that the TACC ( 66 t ) was fully taken (Table 4).

## 2) Pre-recruit indices and recruitment

Current CPUE trends reflect recent increases in both model estimated recruitment and prerecruit indices. Model estimated recruitment to 60 mm CL increased in both zones in 2007 and 2008 (Figure 3). Pre-recruit indices from fixed sites survey (no escape gaps) increased from 2008-2010 (Figure 4). Recruitment to 60 mm CL subsequently entered the fishery 3-4 years later and reflects the current increases to legal size CPUE observed in both zones over the last $2-3$ seasons. However, it is important to note that recruitment to 60 mm CL decreases from 2009-2011 suggesting that fishery recruitment after 2013 may be reduced.

## 3) Puerulus Settlement

Trends in puerulus settlement support current recruitment estimates (Figure 5). Increases to recruitment (at 60 mm CL ) in 2007 and 2008 correlate with high levels of puerulus settlement observed across south-eastern Australia in 2005 and 2006 ( 2 year lag). Further correlations suggest that the period from 60 mm CL to the minimum legal size is a further 3-4 years (Figure 6). In total, this indicates a period of 5-6 years from settlement to legal size within Victoria.

## 4) Model outputs

## Western Zone

The latest stock assessment model outputs estimate Western Zone egg production in 2011/12 at $74 \%$ of the egg production in the reference year 2001/02 (well above the $35 \%$ limit) (Figure 7). Available biomass was $75 \%$ of the available biomass at 2001/02 (well below the $173 \%$ target). The model $50 \%$ probability forward projection indicates that for a fully taken Total Allowable Commercial Catch (TACC) of 259 t , the available biomass would rebuild to the target within 9 years (by 2020/21) (Figure 8).

## Eastern Zone

Eastern zone egg production in 2011/12 was 148\% of the egg production in the reference year 2001/02 (above the limit of 104\%) (Figure 9). Available biomass in 2011/12 was 126\% of available biomass in 2001/02 (well below the 219\% target). The model $50 \%$ probability forward projection indicates that for a fully taken TACC of 51 t , the available biomass would rebuild to the target within 9 years (by 2020/21) (Figure 10).

Tables and Figures
Table 1. Western Zone catch, fishing effort and CPUE

| Fishing year | Catch (tonne) | $\begin{aligned} & \text { Catch } \\ & \text { ('000) } \end{aligned}$ | Nominal effort ('000 potlifts) | Nominal CPUE (kg per potlifts) | Standardised CPUE (kg per potlifts) | Mean mass of SRL <br> (kg) | Recreational catch (t) |

Figure 1. Western Zone CPUE from 1951-52 to 2011-12

Figure 2. Eastern Zone CPUE from 1951-51 to 2011-12.

Figure 3. Recruitment to 60 mm CL for Western Zone (WZ) and Eastern Zone (EZ) fisheries as used in the length-frequency model. Long-term historical average (solid black line) also indicated.

Figure 4. Western (top) and Eastern (bottom) Zone fixed site monitoring CPUE trends.

WZ comparison of puerulus with $60-\mathrm{mm}$ SRL model projections

Fishing year

Figure 5. Model estimated recruitment to 60 mm CL in the Western Zone (WZ) fishery (green line) with puerulus settlement from Port Campbell (blue line) and Apollo Bay (pink line), lagged by two years. Note: Absence of puerulus data at Apollo Bay (2007-2008) due to harbour development.

WZ comparison of fixed-site survey with $\mathbf{6 0 - m m}$ SRL model projections

Figure 6. Comparison of model estimated recruitment to 60 mm CL in the Western Zone (WZ) (green line) with undersized (red line) lagged by two years and legal sized (black line) lagged by four years.

Figure 7. Model estimated level of egg production through time in the Western Zone (WZ) (with 75\% probability; black line). Limit reference point (35\% of egg production in 2001; dashed red line). Projected egg production (dashed blue line) given a TACC of $259 \mathrm{t} / \mathrm{yr}$, to rebuild available biomass to the biological reference point target by 2020

Figure 8. Model estimated levels of available biomass in the Western Zone (WZ) (with 50\% probability; black line). Target reference point (173\% of available biomass in 2001; dashed green line). Projected available biomass (dashed blue line) given a TACC of $259 \mathrm{t} / \mathrm{yr}$ to rebuild available biomass to the biological reference point target by 2020.

Figure 9. Model estimated level of egg production through time in the Eastern Zone (EZ) (with 75\% probability; black line). Limit reference point (104\% of egg production in 2001; dashed red line). Projected egg production (dashed blue line) given a TACC of $51 \mathrm{t} / \mathrm{yr}$ to rebuild available biomass to the biological reference point target by 2020.

Figure 10. Model estimated levels of available biomass in the Eastern Zone (EZ) (with 50\% probability; black line). Target reference point (173\% of available biomass in 2001; dashed green line). Projected available biomass (dashed blue line) given a TACC of $51 \mathrm{t} / \mathrm{yr}$ to rebuild available biomass to the biological reference point target by 2020.

## Definitions

| Available biomass | An estimate of the size (weight) of rock lobsters that are above legal minimum length and can be harvested. |
| :---: | :---: |
| Catch per unit effort Nominal | A measure of the density or population size of rock lobsters in the fishery. It is expressed as the effort required to harvest a defined amount of catch. The data has not been altered to remove irregularities in the catch records. |
| Catch per unit effort Standardised | A measure of the density or population size of rock lobsters in the fishery. It is expressed as the effort required to harvest a defined amount of catch. Irregularities in the data set have been removed. |
| Egg production | An estimate of the spawning size of the population. |
| Fishery recruitment | Recruitment to the fishery - rock lobsters have reached legal minimum length and are available to be harvested. |
| Fishing year: Nov September | The period of time when the rock lobster population is considered to be at its peak due to annual recruitment to legal minimum length. It is considered the biological fishing year and the period upon which the stock assessment is based. |
| Fixed-site surveys | Surveys of rock lobster abundance using commercial rock lobster pots (combination of escape gaps open and closed) and research pots (escape gaps closed). |
| Legal minimum length | Carapace length of 105 mm for female and 110 mm for male rock lobsters. |
| Limit reference point | The minimum level of biomass which stock (or equivalent measure such as egg production) must not fall below. |
| Model estimated recruitment | The abundance of rock lobsters up to 60 mm carapace length generated by the stock assessment model. The model uses real data from fixedsite and observer surveys. |
| Pre-recruit indices | A measure of the abundance of all rock lobsters in the population under the legal minimum length. |
| Pre-recruits | All rock lobsters under the legal minimum length. |
| Puerulus | After passing through at least 9 oceanic planktonic larval stages, the puerulus stage is an immature form resembling an adult rock lobster. |
| Quota year | 1 July to 30 June. |
| Recruitment | Recruitment to the fishery - rock lobsters have reached legal minimum length and are available to be harvested. |
| Recruits to 60 mm | Juvenile rock lobsters up to 60mm carapace length. |
| Reference year: 2001-02 | The year against which biomass comparisons are made. In 2012, the reference year was changed from 1951 to 2001-02 to reflect the introduction of improved catch and effort data. |
| Target | The stock rebuilding strategy in the Rock Lobster Fishery Management Plan is to rebuild the available biomass to a target equivalent to $40 \%$ of the 1951 biomass by 2020-21. (In changing the reference year to 200102 , the targets also changed: Eastern Zone target is $219 \%$ of the 2001-02 biomass, and Western Zone is $173 \%$ of the 2001-02 biomass). |
